The predictive value of computed tomography (CT) in early massive pulmonary embolism (PE) has not been studied in a cohort of patients presenting with shock. Also, the interrelationship between clinical and CT findings in patients with shock has not been investigated. The purpose of this study was to establish the clinical and radiologic predictors of early massive PE. Twenty-six patients who presented with shock and a suspected PE underwent contrast-enhanced CT. The Wells score was calculated for clinical probability of PE. The independent predictors of early massive PE were: (a) reduced pulmonary arterial flow fraction on CT (RPAFF); (b) signs of right heart strain on CT, i.e. biphasic blood flow (BPF) and reduced spectral flow (SF), and (c) "pulmonary bridge" sign. The presence of RPAFF ($P = 0.0004$), SF ($P = 0.0006$) and BPF ($P = 0.00001$) on CT was also a predictor of early massive PE independently of the clinical probability of PE and shock. Also, a direct relationship was found between the severity of the signs of right heart strain on CT and the extent of thrombo f678ea9f9e
